# USACE – Overview of Modeling Approach and Enhancements

---

RiverWare User Group Meeting  
August 13-14, 2008

David Neumann

# Outline

---

- Summary of methods and how they work together
- New functionality
  - Cumulative Flow Disagg (previous presentation)
  - Iterative mode and yield study (later presentation)
  - Alternative routing coefficients
  - Initialization for routing
- Upcoming Work

# Overview

---

- Methods and rule functions are used to replace the approach used by USACE in the SUPER program
  - Flood Control
    - Surcharge Release
    - Regulation Discharge
    - Flood Control Releases
  - Conservation Operations
    - Low Flow / Demand Releases
    - Reservoir Diversions
    - Reach Diversions
    - Hydropower

# Surcharge

---

- Mandatory releases made regardless of downstream channel constraints
- Pool elevation exceeds top of the flood pool
- Ensures safety of the structure

**Rule:** Set Surcharge Release Flag (S) on Res.Outflow slot of each Reservoir in Computational Subbasin

**Simulation:** Surcharge releases and Outflows are computed and set by the resulting dispatch method for entire forecast period

# Regulation Discharge

---

- Methods determine the maximum flow permitted at the control point and empty space available in the channel based on the current flow

**Rule:** Set Regulation Discharge (G) Flag on all Control Point.RegDischargeCalc slots

**Simulation:** Calculate Regulation Discharge and dependent methods; removes G flag; does not reset any Outflows

# Flood Control

---

- Determine additional flood control releases for each reservoir in the subbasin
- Respect downstream channel constraints
- Balance reservoir storages to extent possible

**Rule: FloodControl():** Function executes Flood Control Method on subbasin and the calling rule sets Reservoir.FloodRelease and Res.Outflow on subbasin (outflow = surcharge release + flood release)

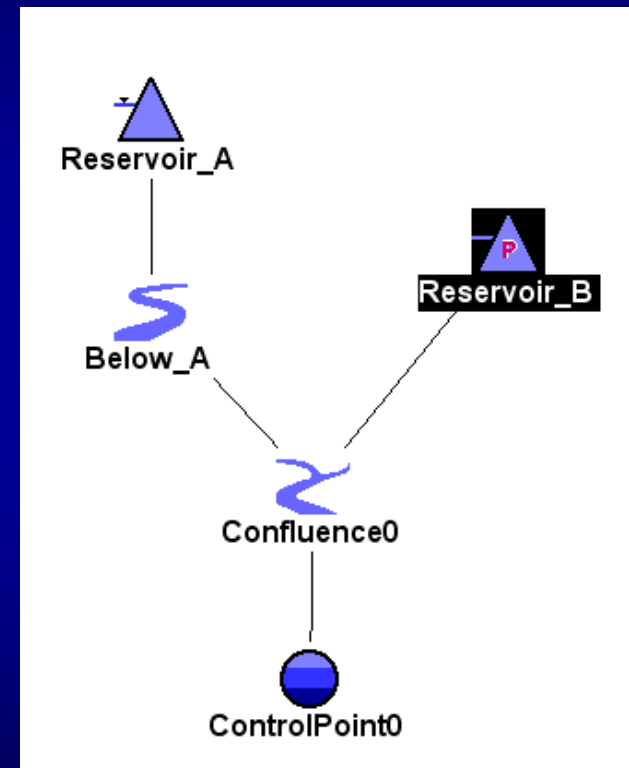

**Simulation:** Objects dispatch and results propagate downstream

# Conservation Operations: Low Flow / Demand Releases

- Flow requirement on a Control Point represents environmental flows or demand
- Determine releases to meet a downstream flow requirement
- Reservoirs are considered in the order of highest operating level

**Rule: MeetLowFlowRequirement():** Execute Low Flow Release Method on computational subbasin and rule sets reservoirs Low Flow Release slots and Outflow slots

**Simulation:** Objects dispatch and results propagate downstream

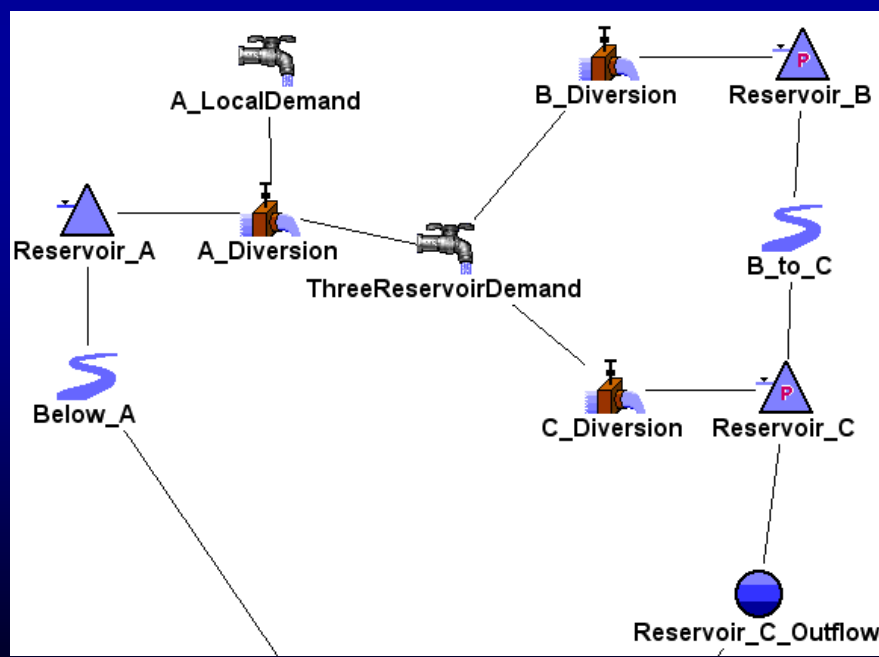

# Conservation Operations: Reservoir Diversions

- Water is diverted directly out of a reservoir to meet demands
- Modeled using a Diversion and Water User
- One reservoir can meet many demands
- A demand can be served by many reservoirs

**Rule: ComputeReservoirDiversions():**  
Execute method on subbasin and set Water Users' Incoming Available Water subslots and Diversion objects' Multi Outflow slots

**Simulation:** Reservoirs, Water Users, and Diversion objects dispatch.

# Hydropower

---

- Make releases to meet energy demand
  - Cannot draw below min power pool or exceed max drawdown
  - Cannot cause additional downstream flooding

**Rule: HydropowerRelease():** Prioritizes the reservoirs by relative energy shortage.

- Loops through each reservoir in the basin and calculates the proposed release to meet the demand.
  - Calculates portion of the proposed release that will not cause additional downstream flooding.
  - Rule sets Res.Outflow
- **Simulation:** Objects dispatch simulating the effects of the release.

# How does this all work together:

---

- Rules execute in following order once per ts:
  - Surcharge Release } Mandatory Releases
  - Regulation Discharge } Find Empty Space
  - Flood Control Releases } Additional Flood Releases
  - Low Flow / Demand releases } Increase Outflow
  - Reservoir Diversions } Divert water from Res.
  - Hydropower } Increase Outflow

Note, reach diversions and losses happen as objects dispatch.

# Recent Enhancements

---

- Calculation of incremental flows from cumulative – see previous presentation
- Iterative Mode MRM / Yield Study
  - Integer Index Slots
  - Yield Study Algorithms
  - Presented in detail later

# Alternative Routing

- During high flow periods, overbank flow causes invalid routing coefficients.
- New Reach routing method: Variable Step Response
- Reach uses Inflows to select step coefficients

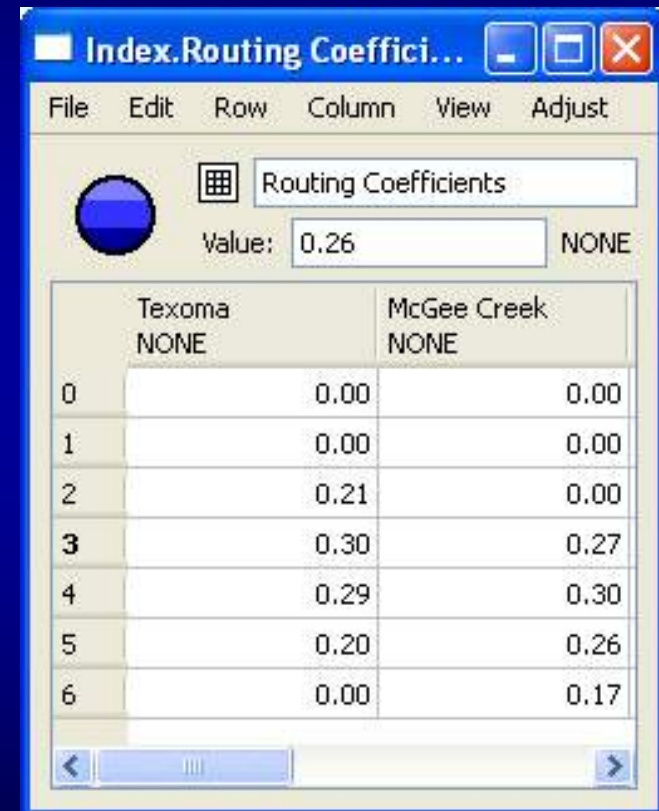

Variable Lag Coefficients

Value: 0.2162 NONE

	0 cfs ---	80000 cfs ---	150000 cfs ---

12	0.0000	0.0000	0.0006
13	0.0000	0.0000	0.0003

# Alternative Routing – USACE methods

- USACE methods also needed to be enhanced
- Flood control uses slots on CP to specify how water routes from each res to a given CP
- These were static – now they are generated at each timestep

The screenshot shows a software window titled "Index.Routing Coeffici...". The window has a menu bar with "File", "Edit", "Row", "Column", "View", and "Adjust". Below the menu bar is a toolbar with a grid icon and a text box labeled "Routing Coefficients" containing the value "0.26". To the right of the text box is a dropdown menu currently set to "NONE". Below this is a table with two columns: "Texoma" and "McGee Creek". Each column has a sub-column labeled "NONE". The table has seven rows, numbered 0 to 6. The values in the table are as follows:

	Texoma NONE	McGee Creek NONE
0	0.00	0.00
1	0.00	0.00
2	0.21	0.00
3	0.30	0.27
4	0.29	0.30
5	0.20	0.26
6	0.00	0.17

# Alternative Routing - USACE methods

---

- Methods added to Computational Subbasin to specify objects of interest and methods to CP to hold slots
- On each CP, the method searches upstream and uses
  - start of timestep flows and
  - coefficients on reachesto create aggregate coefficients from a CP to each upstream Reservoirs
- New coefficients are stored on temp slots

# Alternative Routing – Flood Control Modifications

---

- Flood Control function now uses temp aggregate coefficients in all calculations
- Note, in simulation the reaches still use the coefficients based on inflows – conservation of mass

# Initialization for Routing - Background

- USACE methods required that all objects can solve on first timestep
- Because of routing, user has to input pre-simulation data. Difficulties include:
  - Time consuming to calculate number of timesteps needed
  - Which slots need data?
  - Time consuming to enter data
- Hard to move model forward in time
- Approach: New method on Computational Subbasin “Initialize Flow Slots for Routing”

# Initialization steps

---

RiverWare searches through the subbasin and determines:

1. Slots that need to be set:
  - Reach, Confluence, Gage, Agg Reach: Inflows (if not linked)
  - Reservoir, Inline Power, Pipeline and Inline Pump: Outflows (if linked)
  - Reach: Local Inflows, Diversion, and Return Flows (if linked)
2. Number of pre-simulation timesteps required for each object.slot of interest. Each object searches routing reaches downstream to bottom of subbasin. E.g. 3 day lag = 3 timesteps

# Initialization steps (cont.)

---

3. The value to set on each slot. User methods are available to backcast:
  - Zero
  - Initial Value - First user input
4. Finally, the method sets the value on the slot

Dierks.Outflow [@ 6/27/56] -- Volume: 0.00 [ft<sup>3</sup>]  
1 value: 0.00 [cfs]

➤ Multiple subbasins can be defined

- Backcast a value for certain object.slots (e.g. Res.Outflow)
- Assume a value of zero for others (e.g. Reach.Local Inflow)

# Upcoming Enhancements

---

- Performance work
- Export/Import plot configurations
- Post processing to create monthly reports
- Create formatted printable text file of objects, methods, tables, notes in model
- Clear values imported by DMI
- Extend riverwareDB for data objects
- User Guide for USACE methods
